

REMARKS

Applicant respectfully requests that the above-identified application be amended to delete claims 1-6 and insert new claims 7-18. Additionally, Applicant submits herewith a clean version of a substitute specification and a marked-up version of the specification as filed. This substitute specification includes no new matter.

If the Examiner has any questions regarding this application, Applicant's attorney may be reached at (248) 647-6000.

Attached hereto is a marked-up version of the changes made to the specification and claims by the current amendment. The attached page is captioned "Version with Markings to Show Changes Made."

Respectfully submitted,

Thomas E. Anderson, Reg. No. 31,318
Gifford, Krass, Groh, Sprinkle,

VERSION WITH MARKINGS TO SHOW CHANGES MADE

IN THE ABSTRACT:

A new abstract has been added to replace the one originally filed.

IN THE SPECIFICATION:

The specification has been replaced with the substitute specification submitted herewith. A marked-up specification is also submitted herewith.

IN THE CLAIMS:

Claims 1-6 have been canceled.

New claims 7-18 have been added.

FIXING ELEMENT FOR FIXING CORRUGATED TUBES TO A SUPPORT PART

[Description] Background of the Invention

Field of the Invention

5 The invention pertains to a fixing element for fixing corrugated tubes to a support part[, wherein the]. The fixing element [can be connected] is connected to the support part by [means of] a fixing leg[,] and [wherein the fixing element contains] includes engaging members that [can be engaged with] engage undercuts provided on the corrugated tube.

10 Reference to Related Art

Corrugated tubes [serve, for example, for accommodating] are often used in the installation of electric lines or bundles of cables that [should] extend or [be] are installed along a support part. Due to the design [which is in the form of a] of the corrugated tube[,] (i.e., a tube with uniformly spaced apart
15 circular grooves or ribs in its outer surface), the tubes [of this type] are very flexible such that a bundle of cables can be arbitrarily installed in a space-saving fashion[, e.g., such that it]. For example, the tube may be installed such that it follows the shape of a support part[, while being covered and protected].
In order to fix a corrugated tube with a bundle of cables situated therein at its
20 intended location, [it] the tube needs to be fixed to the support part [in question within] at certain intervals. For this purpose, the ribbed outer surface of the corrugated tube is[, for example,] typically provided with two undercuts that extend parallel to one another in the longitudinal direction in a mirror-inverted fashion[, wherein fixing]. Fixing elements are then arranged on the support

part [within] at certain intervals [are able to engage behind said undercuts] and
are engageable with the undercuts of the tube.

Corrugated tubes of this type are available with various diameters. In
corrugated tubes with a relatively small diameter and an accordingly thin wall,
5 the above-mentioned undercuts also are relatively small such that they only
provide a small engaging surface for a fixing clamp [and the connection may
not appear sufficiently secure]. Therefore the connection between the
undercuts of the corrugated tubes and the fixing element may not be
sufficiently secure to ensure proper installation of the tube.

10 Summary of the Invention

The invention [is based on the objective of developing] is directed to a
fixing element [for reliably fixing, in particular,] for securely and reliably
attaching corrugated tubes [with] having a relatively small diameter and
undercuts (with an accordingly small depth) to a support part.

15 According to the invention, [this objective is attained due to the fact
that] there is disclosed a fixing element having a guiding rail that is rigidly
connected to the fixing leg of the fixing element[, wherein a]. A slide with a
retainer lock [that] is tapered in the inserting direction and rigidly arranged on
the slide and can be displaced in [said] the guiding rail[, wherein engaging].
20 Engaging edges that extend toward one another in a mirror-inverted fashion are
formed on one side wall of the guiding rail and on the retainer lock surface of
the retainer lock which is situated opposite to the aforementioned side wall of
the guiding rail[, wherein said]. The engaging edges [can be engaged] are

engageable with undercuts on the corrugated tube to be fixed [which]. The undercuts extend parallel to one another in the longitudinal direction in a mirror-inverted fashion[, and wherein the]. The distance between the engaging edges is reduced when the slide is inserted into the guiding rail.

5 The slide can preferably assume two positions in the guiding rail. [The] A disengaged position is characterized by the slide being partially pulled out of the guiding rail and the distance between the engaging edges being at its greatest. [The] An engaged position is characterized by the slide being inserted into the guiding rail and the distance between the engaging edges being
10 reduced.

 In the disengaged position of the slide, the undercuts of the corrugated tube to be fixed [which extend parallel to one another in the longitudinal direction] are engaged with the [correspondingly spaced apart] engaging edges that are integrally formed onto one side wall of the guiding rail and the
15 opposing retainer lock surface of the retainer lock. [When] Preferably, when the slide is inserted into the guiding rail, the distance between the two engaging edges is reduced (due to the wedge effect of the retainer lock arranged on the slide) such that the engagement with the undercuts on the corrugated tube is tightened and a secure retention of the corrugated tube is [also] ensured [if the
20 engaging surface on the undercuts is relatively small].

 [The] Preferably, the guiding rail contains bottom and side walls with guiding surfaces for the slide. An engaging tab that is slightly bent upward and contains an upwardly directed locking tab is advantageously formed on the

base of the guiding rail by means of recesses[, wherein said]. Preferably, the
engaging tab can be elastically engaged with notches provided on the underside
of the slide [at a distance from one another which defines] which defined the
disengaged position [of the slide and at a distance from one another which
5 defines] and the engaged position of the slide. [Due to this measure]
Therefore, the slide is held in the guide rail in a captive fashion in its
disengaged position and locked in its engaged position such that an
unintentional disengaging of the corrugated tube from the fixing element is
prevented.

10 According to [one] a preferred embodiment of the invention, the slide
[consists of] has a flat base part that carries the retainer lock on its upper side.
The slide is guided on guiding surfaces formed by the side wall of the guiding
rail on one side and by a step of the side wall of the guide rail on the other side
by [means of] an outer retainer lock surface and an inner lateral surface of its
15 base part.

The slide is preferably guided on one side in a rectangular groove
formed in the side wall and on the other side in a rectangular groove formed
underneath the step, namely by [means of] guiding ridges that laterally
protrude from the base part.

20 [According to one preferred embodiment of the invention, the] The
guiding surfaces for the slide (which are formed on the side walls of the
guiding rail) extend transversely in reference to the center line of the base[,
wherein the]. The base part of the slide transversely extends at the same angle.

[In this case] Therefore, one engaging edge formed on the inner retainer lock surface and the opposing engaging edge formed on one side wall of the guiding rail above the step that forms a guiding surface for the base part of the slide extend parallel in reference to the center line of the base of the guiding rail.

- 5 Due to these measures, a superior clamping effect of the engaging edges on the undercuts of the corrugated tube is achieved.

Brief Description of the Drawings

The invention is described in greater detail below with reference to the enclosed figures; the figures show:

- 10 Figure 1, a side view of a corrugated tube with undercuts for fixing the corrugated tube which extend in the longitudinal direction on its underside;

Figure 2, a view of the corrugated tube shown in Figure 1 which is directed onto one opening of the corrugated tube;

- 15 Figure 3, a perspective view of a fixing element according to the invention;

Figure 4, a side view of the fixing element shown in Figure 3;

Figure 5, a top view of the fixing element shown in Figure 3;

Figure 6, a cross section through the fixing element along the line of section VI-VI in Figure 4, namely with the fixing ridge clamped in position;

- 20 Figure 7, a top view of the base body of the fixing element shown in Figure 3;

Figure 8, a longitudinal section through the base body of the fixing element along the line of section VIII-VIII in Figure 7;

Figure 9, a cross section through the base body of the fixing element along the line of section IX-IX in Figure 8;

Figure 10, a top view of the slide of the fixing element shown in Figure 3;

5 Figure 11, a side view of the slide shown in Figure 10, and

Detailed Description

10 Referring now to Figures 1 and 2 [respectively show a generally known] there is shown a corrugated tube 1 in the form of a side view and a view that is directed onto one of the tube openings. The [typical] ribs 3₁ which provide the corrugated tube 1 with its flexibility₁ are produced by arranging circular grooves 2 in the outer surface of the tube. In Figures 1 and 2, the underside of the corrugated tube 1 is provided with two undercuts 4 that extend

15 parallel to one another in the longitudinal direction in a mirror-inverted fashion such that a fixing ridge 5₁ which is integrally formed onto the outer surface of the corrugated tube 1₁ is created. The corrugated tube 1 can be cut open in the longitudinal direction such that a bundle of cables to be installed can be placed into the corrugated tube 1 [through the thusly formed slot that can be bent

20 open]. One characteristic of the plastic material that is preferably used for the corrugated tube 1 is that the slot closes again after a bundle of cables is placed into the corrugated tube.

10031694 "012202

5 The corrugated tube 1 can be inserted or pressed into a fixing element that is arranged on a [not-shown] support part (not shown) [with] by its fixing ridge 5 in such a way that engaging members provided on the fixing element engage behind the undercuts 4 of the fixing ridge 5 [and a] to secure [retention of] the corrugated tube 1 on the support part [is achieved]. The slot for inserting the bundle of cables into the corrugated tube 1 is preferably produced outside of the fixing ridge 5, in particular, on the opposite side of the corrugated tube. Due to this measure, one or more bundles of cables can also be subsequently inserted into the corrugated tube 1. Naturally, it would also be possible to pull a bundle of cables through [the] a non-slotted corrugated tube 1 and to anchor the corrugated tube on the fixing element with its fixing ridge 5. In special applications, it may be necessary to arrange the slot in the fixing ridge 5. In this case, the slot is preferably produced along [the] a center line of the fixing ridge 5. After the fixing ridge 5 with its undercuts 4 is engaged with the engaging members of [the] a fixing element, the slot is compressed such that the corrugated tube 1 is held closed. This may provide an additional safety in certain instances.

10

15

20 In corrugated tubes 1 with a relatively small diameter and a relatively thin wall 6, the undercuts 4 also are accordingly small such that they frequently do not provide a sufficient engaging surface for known fixing elements [in order to ensure a truly secure retention on the support part]. Therefore, it is difficult to ensure that these small tubes are properly secured to the fixing

element and to the support part. The fixing element 7 according to the invention serves for eliminating this problem.

Referring now to Figure 3 [shows] there is shown a perspective representation of [the new] a fixing element 7[,] constructed in accordance with the present invention. [and] Figure 4 shows a side view of the [same] fixing element 7. [This] Preferably, the fixing element 7 [essentially consists of] includes [two parts, namely] a base body 8 [with] having a guiding rail 9 and a fixing leg 10, [as well as] and a slide 11 having a retainer lock 12 (see also Figures 7-12). Figures 4, 6, 8 and 9 indicate that the base body 8 contains a [generally known] fixing leg 10 that can be elastically deformed. The base body 8 [can be inserted] is insertable into an opening of a [not-shown] support part (not shown) with this fixing leg 10 and anchored therein. A circular collar 13 situated above the fixing leg 10 preferably serves [for respectively supporting] to support the base body 8 and the fixing element 7 on [the] a surface of the support part.

[The] Preferably, the guiding rail 9 [which] extends in the longitudinal direction and is situated above [this] the collar 13. The guiding rail 9 [basically] has a cuboid shape, in the upper side of which is arranged a recess 14 that transversely extends in the longitudinal direction [is arranged]. This means that a base 15 and two side walls 16, 17 remain, wherein one side wall 16 widens in the inserting direction P of the slide 11 [(see below)] and the other side wall 17 is tapered in the same direction.

1031694-012202

The tapered side wall 17 contains an inwardly directed step 18 that is aligned with the base part 19 of the slide 11 in the connected state [and thus forms] to form a guiding surface for the slide 11 and a common support surface for the fixing ridge 5 (see Figure 6). A rectangular groove 20 that is raised in reference to the surface of the base 15 is formed underneath the step 18. [The] A free end of the side wall 17 is undercut in such a way that a tapered engaging edge 21 is formed that is directed inward and linearly extends in the longitudinal direction [is formed]. [This] The engaging edge 21 is able to engage behind one of the undercuts 4 on the fixing ridge 5 of a corrugated tube 1 as indicated in Figure 6.

A rectangular groove 22 that is also raised in reference to the surface of the base 15 is arranged in the opposite side wall 16 that widens in the inserting direction P, namely at the same height as the base part 19. An engaging tab 24 that is slightly bent upward and contains an upwardly directed locking tab 25 is formed on the front end of the base 15 by means of recesses 23 arranged on both sides of the tab 25 (see also Figures 7 and 8).

The slide 11 is arranged [where] such that it can be displaced in the [thus formed] guiding rail 9 of the base body 8 (see also Figures 10-12). The slide 11 [consists of] preferably includes an essentially flat base part 19 that is inclined at [a certain] an angle toward an actuating projection 26 which is integrally formed onto the base part 19 in the shape of a T[, wherein said]. Preferably, the angle of the slide 11 corresponds to the transversely extending recess 14 in the guiding rail 9 (see Figure 10). A retainer lock 12 that is

10031694-012202

tapered in the inserting direction P is integrally formed onto the surface of the base part 19. [The] Preferably, the retainer lock 12 is provided with its wedge shape [due to the fact that its] because the outer retainer lock surface 27 extends at the same angle as the base part 19 while [its] the inner retainer lock surface 28 extends perpendicular to the actuating projection 26 (see Figure 10).

5 The inner retainer lock surface 28 is undercut in such a way that, as soon as the slide 11 is inserted into the guiding rail 9, a second engaging edge 29 is created in a mirror-inverted fashion in reference to the engaging edge 21 on the side wall 17 of the guiding rail 9. As indicated in Figure 6, this second engaging edge 21 is preferably [able to engage] engageable behind the second undercut 4 on the fixing ridge 5 of a corrugated tube 1. [The] A lateral surface 31 of the base part 19 [which] that is arranged opposite to the retainer lock surface 27 preferably adjoins the lateral surface of the step 18 in the side wall 17 of the guiding rail 9.

10

15 The slide 11 can assume a disengaged position and an engaged position in the guiding rail 9. For this purpose, the slide 11 is preferably provided with two notches 32 or recesses that are spaced apart on its underside in the longitudinal direction [on its underside]. [The] A locking tab 25 on the elastic engaging tab 24 of the guiding rail 9 is able to engage into these notches 32 (see Figures 11 and 4). [The] A rear notch 32 preferably is arranged directly adjacent to the actuating projection 26. Figures 4 and 5 show the fixing element 7 in the disengaged position of the slide 11, i.e., the locking projection 25 of the engaging tab 24 is engaged with the front [recess] notch 32 which is

20

situated on the underside of the slide 11 at approximately half its length in the embodiment shown (Figure 11). This means that the slide 11 is respectively held in the base body 8 and the guiding rail 9 in a captive fashion in its disengaged position. In this case, the fixing element 7 is in its standby position.

Figure 3 indicates that the slide 11 is guided in the guiding rail 9 by means of guiding ridges 30 and 33 that laterally protrude from the base part 19. For this purpose, one rectangular groove 22 is arranged in the side wall 16 of the guiding rail 9 and another rectangular groove 20 is arranged underneath the step 18. The guiding ridges 30 and 33 are able to engage and slide into these grooves [and slide therein].

When using the fixing element 7, the fixing ridge 5 of a corrugated tube [according to] as shown in Figures 1 and 2[,] (e.g., a corrugated tube into which a bundle of cables was inserted in the previously described fashion)[,] is inserted or pressed into the guiding rail 9 that contains the disengaged slide 11 [with its fixing ridge 5, namely in such a way] such that the opposing engaging edges 21 and 29 on the [guide wall] guiding rail 9 and the retainer lock 12 [of the slide 11] encompass the [guiding ridge [sic; fixing ridge]] fixing ridge 5 of the corrugated tube 1 at the undercuts 4 (see Figure 6). Subsequently, the slide 11 is inserted into the guiding rail 9 (in the direction of the arrow P) until the locking tab 25 of the elastic engaging tab 24 engages into the notch 32 situated closer to the actuating projection 26 on the base 15 of the guiding rail 9 [such that] to lock the slide 11 into an engaged position [is locked in this engaged

position]. Due to the wedge effect of the retainer lock 12, the distance between the engaging [edges] edge 21 on the side wall 17 of the guiding rail 9 and the inner retainer lock surface 28 of the retainer lock 12 is reduced when the slide 11 is inserted into the guiding rail 9 (see also Figure 12). [In this case]

5 Therefore, the engaging edges 21 and 29 are so tightly engaged with the undercuts 4 of the fixing ridge 5 of the corrugated tube 1 that a secure retention of the corrugated tube 1 in the fixing element 7 and consequently on a not-shown support part is also ensured [if the engaging surface for the engaging edges 21, 29 on the undercuts 4 is relatively small].

10

I claim:
